Türk hükümeti mamülleri özellikle ithalat ve satış vergileriyle vergilendirdiği zaman, bunun yükü ham maddelerde de görülecektir. Bu tezde, iki temel amacımız vardır. Birincisi, etkin vergi diye adlandırdığımız bazı vergileri bulmak amacıyla Türkiye ekonomisi için bir model geliştirmektir. Etkin vergideki artış son ürünün fiyatında artışa sebep olacaktır. Ve sonra, Türkiye ekonomisindeki sektörler için etkin vergi değerlerini hesaplayacağız. Bazı insanlar Türkiye ekonomisindeki sektörlerin sosyal olarak faydalı olup olmadığını öğrenmek isteyebilirler. Bu soruya cevap verebilmek için gölge fiyatları bilmek zorundayız. İkinci amacım, Türkiye ekonomisindeki sektörleri faydalı veya faydasız diye sınıflandırabilmek için gölge fiyatları kullanarak sosyal karlılığı hesaplamaktır.

Anahtar kelimeler : Etkin Vergi, Muhasebe Oranı, Standart Çevirim Çarpanı, Gölge Fiyat, Gölge Kar, Sosyal Karlılık

ACKNOWLEDGEMENT

I would like to express my special thanks to my supervisor, Dr. Osman Zaim, for his guide, contributions and comments throughout my thesis. I also would like to express my gratitude to Dr. Nader Habibi and Dr. Syed F. Mahmud for their valuable feedback and evaluations. Finally, I appreciate the help of Dr. Subidey Togan.

1.INTRODUCTION

When Turkish government imposes taxes on commodities, particularly import duties and excise taxes, their burden will also fall on inputs. In this thesis, we have two main objectives. First one is to develop a model for Turkish Economy so as to find a set of taxes t^e for Turkey, which we call effective taxes, so that an increase in the effective tax corresponds to an increase in the price of the final good. In other words, the effective tax t^e is the amount by which government revenue would increase if there were a unit increase in final demand for the good. And then, we will calculate the values of effective taxes for each sector in the input-output table of Turkish Economy.

One also want to know whether a sector in the input-output table of Turkish Economy is socially profitable or not. To answer this question, we have to know shadow prices. My second objective is to calculate social profitability, so that we can classify each sector in the input-output table of Turkish Economy as socially profitable or not, by using Shadow Prices.

A policy-maker in Turkey may want to find a measurement instrument for Turkey, which shows total amount of taxes paid until it reaches consumer, as a percentage of purchaser prices so that he could get an idea about the extent of taxation for each sector in the input-output table of Turkish Economy. This measurement instrument can be effective taxes. Effective taxes would be a

useful summary of statistic for the complicated tax system of Turkish Economy. If this policy-maker were to impose new taxes, or introduce a tax reform for Turkish Economy, effective taxes would be a useful tool for policy-maker. The model, that is used for finding an expression for effective taxes, will be a simple input-output model of open economy, which is based upon the model of Ahmad and Stern (1991).

One may ask the following questions; 'Which sectors in Turkey are socially profitable?, In which sectors, should output be increased or decreased?'. To do this, we have to know shadow prices in Turkey. In principle, shadow prices take into account the full general equilibrium consequences of an extra unit of demand on the system including the effect of changes in government actions. Since shadow prices embody the full effects on social welfare of the extra supply of the good, their calculation requires a general equilibrium model of economy. Since data availability is generally limited, this model should be simple and essentially based on input-output information. We will use the method proposed by Little and Mirrlees (1974), which is based mainly on the information about production to calculate shadow price systems for Turkey. Then, we will use shadow prices to calculate shadow profits, which is defined as shadow value of outputs minus shadow value of inputs (including factors of production). And then, We will try to calculate social profitability, that is the ratio of shadow profit to shadow value of output. Social Profitability is used to determine whether a sector in the input-output table is socially profitable for Turkey or not. So, it will

be useful in the analysis of policy at sectoral level. Shadow prices will also be of value for broad classes of inputs in the analysis of particular investment projects.

The arrangement of thesis will be as follows; In section 2, we will develop a model for Turkish Economy to find an expression for effective taxes and then calculate the value of effective taxes for each sector in the input-output table of Turkish Economy. In section 3, we will give information on shadow prices and show how to calculate them. And then, we will calculate shadow prices and social profitability for Turkish Economy. Finally, we will state our conclusion in section 4.

Literature Review

Ahmad and Stern¹ (1991) presented a set of general principles and methods for the analysis of tax reform in developing countries and examined possible strategies for reform of the tax system in Pakistan. They explored the structure of taxation in Pakistan, reviewed and developed the basic principle of taxation. They also discussed effective taxes and shadow prices in Pakistan. This publication was among important publications in the effective tax literature.

¹ The detailed work in this book was found in the following papers: Ahmad, Barret and Coady (1985) 'Input-output matrices for Pakistan 1980-1'; Ahmad and Stern (1984) 'the theory of tax reform and Indian indirect taxes', Ahmad and Stern (1986) 'Tax reform for Pakistan: Overview and Effective taxes for 1975-76' and Ahmad and Stern (1990) 'Tax reform and shadow prices for Pakistan'.

Metzler (1951), tried to see net effect of taxes in a Leontief's input -output model and showed that the price of taxed goods rises by more than that of untaxed goods. Radhu (1965) tried to see the effect of indirect taxation on prices for Pakistan. Hoffman (1972) tried to see the effect of tax on welfare. Atkinson and Sutherland (1988) use tax-benefit models for optimum taxation.

Newbery (1986), advises that if we could not tax some good even though it must be taxed for optimum taxation, one would want to consider taxing inputs into those goods as a surrogate for taxing final goods. Gersovitz (1987) tried to see the effect of taxes on foreign private investment.

Little and Mirrlees(1974), in their work, advised a method for calculating shadow prices of tradable, non-tradable goods. They used accounting ratios instead of shadow prices and used them to appraise projects.

Ahmad, Coady and Stern (1985), used Little Mirrlees (1974) rule to calculate shadow prices for Pakistan.

Squire and van der Tak (1975), proposed methods to appraise projects. In their work, they mention about investment criteria, distributional weights, the social discount rate, the shadow wage rate, shadow prices for traded and non-traded goods and the standard conversion factor and shadow exchange rate.

Dreze and Stern (1987), has shown how shadow prices can be used to detect welfare improvements arising from a project in an economy with imperfections of various kinds. The analysis provides a framework for the discussion of marginal changes in the government policy in general and shadow prices for investment planning are linked closely to the choice of government policies elsewhere, particularly concerning taxes, trade and the regulation of industry. Dreze and Stern (1990), also tried to find an answer to the question, 'How should public projects and policy reforms be assessed when market prices give misleading signals?'. Revenues and costs at market prices then give distorted measures of social gains and losses and one's appraisal should use social opportunity costs or 'Shadow Prices'. The authors show how shadow prices may be integrated into an analysis of policy reform, demonstrate the critical dependence of these prices on government policy, and analyze their relations with market prices.

In Dixit and Stern (1974), the view of agriculture as facilitating the growth of other sectors was not confined to finance and labour, but included the provision of food to the growing industrial workforce, and the problem of marketed surplus was emphasized. This was among an early analysis of policy models of marketed surplus cooperated with shadow prices.

Heckman (1974) and King (1983) gives an idea about econometric calculation of shadow prices and how those affect welfare of households. Heady

and Mitra (1987) shows how shadow pricing can be employed for optimal taxation. Squire, Little and Durdag (1979) looks at shadow pricing as a macroeconomic policy for Pakistan. Stern (1987) shows how to use shadow prices as a tool for tax reform.

2.EFFECTIVE TAXES

Closed Economy, fixed coefficients; one factor

We begin this section with the simple, static closed-economy Leontieff model, and then turn to open economy.

All purchasers of a good pay a price with tax included. The purchasers' price vector q is defined as the price paid by consumers and is also paid by producers for the purchase of inputs. The producers' price vector p represents the price received by producers for sales. Consider the simple input-output model of production with fixed input-output matrix A , gross output vector Y , and net output vector Z . Then inputs are AY , and

$$Z = Y - AY = (I - A) Y \quad (1)$$

Competitive price conditions for this model are

$$p' = q' A + v' \quad (2)$$

where primes denote row vectors and v is the vector of per unit value added by industry. (For the moment , assume it to be fixed- You may think of it as the vector of labor requirements \times the wage)

If t denotes the tax vector , then

$$q = p + t \quad (3)$$

and from equations (2) and (3), we have

$$q' = t' \times (I - A)^{-1} + v' \times (I - A)^{-1} \quad (4)$$

In this model, the effective tax vector t^e is,

$$t^e = t' \times (I - A)^{-1} \quad (5)$$

Open Economy, fixed coefficients; one factor

Let us Introduce exports and imports into our model. Furthermore, let superscripts m and d refer to imported and domestic goods respectively. Unless otherwise stated, all imports are assumed to be complementary; that is, production of good j at unit level requires a_{ij}^d of good i produced domestically and

a_{ij}^m of imported good i . In the absence of taxes, the competitive pricing conditions for domestically produced goods becomes

$$q' = q' A^d + v' \quad (6)$$

where A^d is a matrix of input-output coefficients for domestic flows. The foreign exchange costs ($p_m' A_m$ where p_m stands for import prices) of imported inputs have been included in the vector of value added, v , and there are assumed to be no import quotas for these inputs. If we allow for the imposition of excise taxes on domestic production t^d (per unit), and for the import duties t^m (per unit), the pricing equation becomes

$$q' = t^d \times (I - A^d)^{-1} + t^m \times A^m \times (I - A^d)^{-1} + v' \times (I - A^d)^{-1} \quad (7)$$

where A^m is the matrix with the ij th element a_{ij}^m . Thus, the effective taxes t^e , are given by

$$t^e = t^d \times (I - A^d)^{-1} + t^m \times A^m \times (I - A^d)^{-1} \quad (8)$$

In this formulation, the contribution of excise taxes, which fall only on domestic production, to effective taxes is given by $t^d \times (I - A^d)^{-1}$ and that of import duties $t^m \times A^m \times (I - A^d)^{-1}$. Note that in this model the tax effects are additive.

Here, we see domestic and imported inputs as different goods. Hence, we cannot add A^d and A^m to get an aggregate input-output matrix. The effects of sales tax levied on total commodity flows, may also be given by equation (8). There, we can see sales taxes as affecting prices of domestically produced goods in part through domestic inputs. In the discussion of effective taxes, we will ignore the income tax.

Finally, we can take into account the taxation of goods which arises through the capital stocks required in their production. By replacing A^d by $(A^d + r K^d)$ and A^m by $(A^m + r K^m)$ where K^d is the matrix of stocks of domestic goods required as capital for the production of domestic goods, K^m the matrix of stocks of imported capital goods for domestic production, and r a real rate of interest², we can modify formula (8) in a steady state framework. The steady state assumption is necessary since otherwise we would have to consider carefully the time pattern of accumulation, taxes and rates of interest in the determination of prices.

Data

In this study, we needed information on revenue collections for the indirect taxes, and tables of input-output coefficients for absorptions of domestic and

² See Ahmad and Stern (1991)

imported goods and services. At the time of my study, the latest available table was for the year 1990.

We assume exports not to enter into the domestic production circuit. Thus export duties do not affect the calculation of effective taxes. However, if world prices are fixed, then export taxes would be shifted backwards onto factors of production. During our reference period, export duties in Turkey were completely lifted .

Data on import and indirect tax collections for the year 1990 have been obtained from the input-output table of the same year. It is a known fact that excise taxes also applied to imported goods. Proportion of imports to total commodities is given by national accounts. This information can be used to find the part of indirect taxes received from imported commodities. Remaining part of total indirect taxes will be total tax collections from domestically produced commodities. Adding the indirect taxes collected from imported commodities to import duties yields tax revenues of imported goods. The nominal tax rates for domestically produced t^d and imported goods t^m will be found as follows: Dividing revenues for each good by flows of the good, we derive the implicit rate of tax, which we call the nominal rate. This way of calculating nominal rates, circumvents the problem of evasion associated with the use of announced statutory changes. Moreover actual collections provide a weighted average of the implicit tax rates for any commodity group.

The input-output matrix used in this fieldwork was obtained from the State Institute of Statistics. It was an 64-sector matrix of domestic and import flows at purchaser prices. We know proportion of imports to total commodity in circulation. Thus, we have estimates for both imported and domestic coefficient matrices, A^m and A^d .

Finally, we need a data set to estimate a capital stock matrix. Investment data was also available in input-output table. Assume that all assets depreciate by a fraction β per year and that a fraction α of the current investment (a matrix) is used for replacement , then $K = (\alpha/\beta) \times I$ and $r \times K = r \times (\alpha/\beta) \times I$. We have to take into account the resources, $\alpha \times I$, used for replacement. We assume that these are not captured in the input-output matrix. Hence we must augment A by $[r \times (\alpha/\beta) + \alpha]$ times the investment matrix. If there were no information on α and β , we would have taken this factor to be unity. One case consistent with this assumption is $r = \beta$ and $\alpha = 1/2$. By taking the investment for each sector and allocating it across the various investment sectors using the proportions given by the national accounts, we constructed investment matrix. The resulting matrix is divided into assets which are imported and those which have been domestically produced using the proportions of the absorption of imports and domestic goods in 1990. Real interest rate for the year 1990 was negative. (-3.9) It would be insensible to use this value as a real interest rate, since one may expect that using capital should have some cost to the user. One may propose different

methods to obtain real interest rate. One method was to take average of last 20 years real interest rate, which would turn out to be about 3%. Another method was to take the average of last 20 years growth rates, which would turn out to be approximately 4.8%. (note that in growth theory, in long run golden rule holds, which says growth rate = real interest rate). We will experiment with 3%, 4% and 5% values of real interest rate.

The Effective-tax Calculation

We can divide the effective-tax estimates for the year 1990 into the component domestic t_e^d , arising from domestic sources , and imported sources t_e^m , arising from inputs of imported goods into domestic production as shown in equation (8).

$$t_e^{d'} = t^{d'} \times [I - A^d]^{-1} \quad (9)$$

$$t_e^{m'} = t^{m'} \times A^m \times [I - A^d]^{-1} \quad (10)$$

These are modified as we consider the tax element in price attributable to the taxation of capital assets. So modified components of effective taxes will be as follows;

$$\bar{t}_e^d = t^d \times [I - \bar{A}^d]^{-1} \quad (9')$$

$$\bar{t}_e^m = t^m \times \bar{A}^m \times [I - \bar{A}^d]^{-1} \quad (10')$$

where \bar{A}^m , \bar{A}^d are the matrices of imported good requirements modified by the capital inputs and the capital-augmented domestic good matrix, respectively. We define \bar{t}_e^m and \bar{t}_e^d to be the effective taxes on domestic goods arising from import taxation and domestic taxation, respectively. The total effective tax including the effects arising from assets is

$$\bar{t}_e = \bar{t}_e^d + \bar{t}_e^m \quad (11)$$

In table I.1, I.2, and I.3, you will see estimates of t_e^m and \bar{t}_e^m which arises from the taxation of imported inputs into domestic production for the real interest 3%, 4% and 5%, respectively. All comments are made for the real interest rate 4%. All domestic commodities except public services are affected by the taxation of imported inputs. It is below 3% of purchaser price for most of the commodities. It can be noted that the highest imported sources of effective-taxes, at around 6% of purchaser prices, is observed for Manufacture of Land Transport Vehicles and Equipment, Manufacture of Petroleum and Coal Products, and Manufacture of Plastic Products. When the taxation of the imported capital stock is taken into account, there is change in the imported

source of effective taxes and \bar{t}_e^m is less than t_e^m , for most of the commodity groups. The taxation arising through imported goods ($\bar{t}_e^m - t_e^m$) subtracts less than 1% from purchaser prices of most items. The most affected sectors by taxation of capital stock were Manufacture of Other Transport Equipment (9.3%), Other Construction (8%) and Building Construction (7.9%). We may move on to next table by saying that the taxation of imported capital goods form a significant contribution to the to the value of \bar{t}_e^m for all goods except Public Services, which was already untaxed.

We are also interested in the part of taxation arising through domestic intermediate inputs (Table II's) and this is measured by the divergence \bar{t}_{diff}^d between the domestic effective tax t_e^d and nominal tax on domestic production t^d

$$\bar{t}_{diff}^d = \bar{t}_e^d - t^d \quad (12)$$

It is, generally, between 0.75 and 24% of purchaser prices for most of commodities, 0 for Public Services. It is above 10 % of purchaser prices for Other Construction (24), Building Construction (21%), Manufacture of Other Transport Equipment (17%), Manufacture of Agricultural Machinery and Equipment (15%), Manufacture of Petroleum and Coal Products (12.8%), Manufacture of Railroad Equipment (12%), Manufacture of Shipbuilding and Repairing(10)

The overall effective tax, from both domestic and imported sources, is shown in Table III's. t^d in the first column stands for nominal tax on domestic production. In columns 2 and 3, the effective taxes with and without the effects of taxation of the capital stock, t_e and \bar{t}_e are shown respectively. All commodity groups except public services are affected by the structure of indirect taxes. In some cases, effective taxes are quite high, as for Other Construction, for which the effective tax as a proportion of purchaser prices is around 35%. High effective taxes may reflect high nominal taxes, and Petroleum Refineries is a case in this point. It is the difference between effective and nominal taxes, \bar{t}_{diff} , which reflects taxation arising through other commodities and assets, and which may sometimes be a unintended consequence of a government policy. In case of Other Construction, \bar{t}_{diff} is actually around 35% of purchaser prices. For Building Construction, it is about 31% of purchaser prices. For Railway Transport, it was about 11.5% of purchaser prices. In reality, the only subsidized sector is Railway Transport, for which \bar{t}_e was about -8%. The case of Other Construction is a good example of seeing effect of taxes falling over taxes. In agriculture, Sugar, Manufacture of Petroleum and other Coal products, and Water transport, we observed effective taxes to be positive even though they seem to be subsidized. The inclusion of taxation of capital stock has had a small, insignificant impact on producer prices except for the Public Services. For most of the commodities, $\bar{t}_e - t_e$ is smaller than 1% of purchaser prices

3.SHADOW PRICES

Let us first describe the basic elements of the shadow price system. There are two main elements.

- (i) For traded goods, relative shadow prices should be equal to relative world prices.
- (ii) for non-traded goods, the shadow price is the marginal cost of production evaluated at shadow prices.

Basically, world prices represents the net benefits on the margin associated with an adjustment to production or consumption of traded good. For example, if a good is traded at fixed prices, the effect of an expansion in the production is not to change prices and the welfare of the households directly, but simply to save imports or increase exports. Therefore, all that matters is the foreign exchange earnings or savings. These foreign exchange earnings may have a different value from that given by the official exchange rate, but relative values of goods are given by their relative world prices.

Another point is the desirability of public sector efficiency. Given that the public sector should be efficient, the marginal rates of transformation between a pair of goods should be the same wherever those goods are transformed one into the other. When economy becomes an open economy, the marginal rates of

transformation in that activity becomes equal to the relative world prices. Therefore, these should be the marginal rates of transformation elsewhere and thus the relative shadow prices to be used for evaluating projects.

We now turn to non-traded goods. The Little-Mirrlees rule is that the shadow price is the marginal cost of production at shadow prices. Let w_j stand for the shadow value of domestic factors used directly in the production of good j and μ_j for the shadow value of the tradable inputs which are direct inputs into good j . Then, for the m non-tradable goods, indexed by $j=1, \dots, m$, we have

$$v_j = \sum_k v_k a_{kj} + w_j + \mu_j \quad (13)$$

where v_j is the shadow price of non-tradable good j and a_{kj} is the marginal amount of good k required for the production of a unit of good j . In matrix notation, we have

$$v' = v' \times A + w' + \mu' \quad (14)$$

and

$$v' = (w' + \mu') \times (I - A)^{-1} \quad (14')$$

where a prime denotes a row vector and A is the matrix (a_{ki}). Note that theory required us to know the shadow values w of the domestic factors used in the production.

When we employ labour on a project, it is diverted from another activity where it was producing and consuming. We must examine how its withdrawal from other activities will affect output and incomes elsewhere, while considering its opportunity cost. Suppose we employ a labourer at a wage c in a public company and that labourer was earning m (his marginal product) in the previous occupation. Then, the consequence of extra employment is that the labour has an extra income ($c-m$) and the public sector loses the wage it has paid c . Then, the social cost of employing the labourer , or the shadow wage rate is

$$SWR = c - \lambda \times (c - m) \quad (15)$$

where λ is the value of the extra income to the labourer as seen by the government.

Consider another aspect of shadow wage which is that the shadow prices for the marginal product (m) elsewhere may not be equal to market prices and the value of c at market prices will not be the same as its value at shadow prices. Hence, we need to convert c and m into shadow prices. To do this, we multiply

each of c and m by a different standard conversion factor or SCF. This converts market prices into shadow prices for a bundle of goods. The make-up of the bundle depends on the problem on the discussion. For m , we would want a bundle relevant to the quantities that worker would have produced if he had been working elsewhere. For c , we need a bundle corresponding to the consumption of the worker. We call the ratio of shadow price to market price, the accounting ratio, and SCF is an appropriate weighted average of accounting ratios. If SCF to be applied to m is 0.75, this says that the shadow prices of goods which would have been produced by the worker elsewhere are 75% of market price, i.e. for traded goods, if these are what would have been produced, the market price is four-thirds of the world price. Then, the reciprocal of the shadow wage rate is like a shadow exchange rate.

Typically, the data for the cost of production will include some element of profit or payment to capital. But, we assume profits to be zero in our fieldwork. Notice that we also have to multiply parts of value added pertaining to capital and land by an appropriate SCF.

Data and some key parameters

Our calculations are based on 64-sector input-output table, the table used for the effective tax calculations. The 64 sectors must be classified into traded and non-traded activities. In the literature, first 49 items in the input-output table

for the Turkish Economy is behaved as tradable and the rest is behaved as non-tradable. For tradable goods, we have to classify them also as exported and imported goods. If the volume of exports (imports) are larger than imports (exports), this commodity group is classified as exported (imported). The non-traded sectors are shown in Table IV.

Once we have obtained information on inputs, outputs and taxes, and classified sectors into tradable and non-tradable sectors, we can find shadow price estimates for Turkey. We consider shadow prices for exportables, importables and non-traded goods in that order. In Table VI, the formulas of shadow prices for non-traded and imported goods is presented. Writing them in matrix form will make life simpler to calculate shadow prices. After writing them in matrix form, you will have two equations and two unknowns. Thus, we will have shadow price estimates for imported and non-traded goods.

We express a shadow price in terms of its accounting ratio (AR) which is the shadow price divided by the market price. For exported goods, this is the ratio of value of exports without taxes to value of exports with export taxes included. So, accounting ratios are 1 for the goods which do not have export taxes. For the year 1990, there were no export taxes or subsidies for exported commodities in Turkey. Thus, accounting ratio is 1 for all exported commodities throughout this fieldwork. The input-output table for the 1990 has data on gross absorptions. In case of imports, subtracting taxes, trade and transport margins

from value of imports, we derive the c.i.f. values. The p_i^{cif} values for importables are shown in Table V.

The calculation of shadow prices requires estimates of the breakdown of the payments to different factor inputs. Such a breakdown can be done by using input-output table. From input-output table, we can find contribution of labour in the value added. The remaining part is due to capital and land. For most of commodity groups, we will assume the share of land to be 0.3. But in some cases, it is different from 0.3. This is done so as to prevent the share of capital from being negative.

To calculate the accounting ratios for non-traded activities, we need those for traded goods and disaggregated value-added terms. For land, we assume throughout an accounting ratio of 0.9. This is somehow a weighted average of accounting ratio for agriculture (exported commodity) and p_i^{cif} value, since one can regard the marginal product of land as being in terms of agricultural goods. For the employment accounting ratio, we experiment with values including 0.9, 0.75 and 0.5. We refer to those ratios as the wage conversation factors (WCF). Lower ARs would correspond to cases where we assume relative abundance of labour.

In a similar manner, an AR for the asset may be generated. We refer to this AR as the asset conversation factor, or ACF. Actual cost of \$1 investment is

$1+r$, r is real interest rate, where nominal cost is $1+n$, n is nominal interest rate. So, we can refer to $(1+r) / (1+n)$ as AR for capital. This value is calculated for the year 1990 and referred as AR for capital.

Shadow price estimates for Turkey

The accounting ratios for non-traded goods corresponding to each combination of ARs for labour and assets are presented in Table VIII. Some ARs are, however, greatly affected by the ARs of major inputs. Also notice that activities with high labour coefficients are most sensitive to the wage conversion factor chosen - for example, (63) 'Public Services'. Similarly, one must expect that those which have high capital coefficients are most sensitive to the asset conversion factor chosen.

One minus the accounting ratio for a sector can be interpreted a shadow subsidy on output in that sector, since it measures the extent to which producers are paid more than the shadow price of their product. It provides a direct commentary on the incentives which have been provided. Another commentary on sectoral priorities and incentives is provided by the analysis in terms of social profitability which involves an examination of the social profitability of expanding exports or domestic productions or imports.

Shadow profits or losses are derived by evaluating the inputs and outputs of each sector at shadow prices. We expect non-traded sectors to have a normal profit at shadow prices, because shadow price is the shadow marginal cost which we have assumed equal to shadow average cost. The classification into traded and non-traded is therefore crucial in interpreting results on social profitability. Recall that there are 49 non-traded sectors.

In Table IX, we present the social profitability (shadow profit or loss as a proportion of the shadow value of output). In this table, we present the sensitivity of the social profitability to ARs for labour ranging from 0.9 to 0.5 for given $AR=0.62$ for the assets.

The list of most socially profitable and non-profitable traded sectors are presented in Table X and XI. Among imported sectors, the most socially profitable sectors are Ginning and Sugar. Canning and Preserving of Fruits and Vegetables are the most socially profitable exported sectors. Petroleum Refineries and Manufacture of Fabricated Metal Products were the most socially non-profitable exported and imported sectors, respectively. Expanding Imports (exports) in imported (exported) sectors, is socially profitable for the Turkish Economy.

For non-tradable goods, the policy interest in the calculations for these sectors lies in examining the shadow marginal cost. For example, we could ask

whether there would be any benefit in the relaxation of import restrictions (if this is the reason why it is non-traded) by comparing the shadow price with the import price. If there appear to be particularly beneficial domestic uses of the non-traded output, we could try to calculate a shadow value for these uses (for example, extra electricity supply). If the shadow value of the use exceeds the shadow marginal cost, then one might argue the output should be expanded and directed towards the beneficial use.

One expects that activities whose outputs have relatively low ARs will exhibit negative social profitability. In our case with a conversion factor for labour of 0.9 and for capital of 0.62, our results suggests, this expectation did not turn out to be true. All commodity groups, showing negative social profitability, except Petroleum Refineries have large ARs. One reason for this situation might be that inputs used in the production of those commodities have large AR's. Note that Animal Husbandry and Manufacture of Fabricated Metal Products, showed positive social profitability as we decreased the conversion factor for labour.

4.CONCLUSION

In this fieldwork, we have presented the calculation of two basic policy tools; Effective taxes and Shadow prices.

We have observed that the ' Effective tax ' differs greatly from the nominal tax. This study may be of use to policy-makers in helping them understand the effects of a complex system, especially when some of these may be unintended consequences of a tax policy. Notice that Effective taxes could be used to provide a quantification of the direct and indirect taxation involved in the domestic production of goods for export.

While calculating shadow prices, we had difficulty in data. Overall, under some assumptions we calculated shadow prices for Turkey. And then, we used them to calculate social profitability for each sector in the input-output table. We have used the shadow price calculations to comment on sectoral policy where shadow prices can be employed to characterize socially profitable activities.

Notes: The third column is the second divided by the first and represents p_1^{cf} , the value of a unit of the importable at c.i.f. prices. Note that units of goods are chosen so that purchaser prices are unity.

Table VI. *Shadow Prices of non-traded and imported goods*

	Non-traded	Traded	Factors
	$p_1^N = p_1^N a_{11} + \dots + p_r^N a_{r1} + \dots + p_n^N a_{n1} + p_i^a a_{i1} + \dots + p_j^a a_{j1} + \dots + p_k^a a_{k1} + p_f a_{f1}$		
Non-traded	$p_r^N = p_1^N a_{1r} + \dots + p_r^N a_{rr} + \dots + p_n^N a_{nr} + p_i^a a_{ir} + \dots + p_j^a a_{jr} + \dots + p_k^a a_{kr} + p_f a_{fr}$		
	$p_n^N = p_1^N a_{1n} + \dots + p_r^N a_{rn} + \dots + p_n^N a_{nn} + p_i^a a_{in} + \dots + p_j^a a_{jn} + \dots + p_k^a a_{kn} + p_f a_{fn}$		
Imported	$p_i^a = \dots 0 \dots + p_r^N a_{ri} +$	$\dots 0 \dots$	$+ p_i^{cr}$

Notes: p_i^a = Shadow price of imported (i to j) and exported (j+1 to k) goods

p_f = Shadow price of factors

p_i^{cr} = Border price (i.e. c.i.f.) of imported goods.

p_i^N = Shadow price of non-traded goods (i+1, ..., r, ..., n)

a_{ij} = Input-output coefficients - ith input per unit production of jth good.

p_r^N = Shadow price for trade and transport, a non-traded good.
